

Create a project using Python + Flask Framework + Mongo DB database

Step 1: You need to create a POST endpoint with request body:

```
{  
  "userInput": "How much should I score in each subject to pass CA final?"  
}
```

Step 2: Store prompts in a MongoDB collection called prompts.

Example document:

```
{  
  "_id": "Education_Prompt",  
  "template": "You are an expert in education domain. Answer the following: {{userInput}}"  
}
```

Step 3: ChatGPT API Call

- Replace {{userInput}} with request body input.
- Call OpenAI API with the final prompt.

Step 4: Store Request/Response

Save every request/response pair into a new Mongo collection (history)

Step 5: Return Response:

Return response received from ChatGPT API in JSON format.

```
{  
  "response": "....."  
}
```

Step 6: Create another POST end point and instead of sending a single string, the client will send a **list of strings** in one request.

- The system must **fetch the prompt from NoSQL**,
- Process **each string independently** with the ChatGPT API,
- Run the calls **asynchronously** (so multiple requests don't block each other),

- Return a **list of AI responses** in the same order.

Note: You are required to build this project on your own. Use any references you need, but do not submit auto-generated code. We will ask you to explain your design choices, database schema, and code logic during the review. Submissions that look copy-pasted without understanding will not be accepted.
